

General Info

When using a UNIX system it is sometimes necessary to change file permissions. This is done using the CHMOD command. There are two different ways to chmod a file.

Certain FTP clients such as Cute FTP and WS/FTP Pro allow for chmoding directly within FTP. To do this you would highlight the file that you want to use, and select from the command menu "change file permissions." There is an option for "manual." This is where you will enter the desired CHMOD. Many other FTP clients will support CHMODing as well, we recommend checking the documentation.
